ABSTRACT
In current study, NH₄⁺ cation and Al metal concentrations in summer period were determined by ultraviolet-visible (UV-VIS) spectrophotometric technique in the total 6 swimming pools found in the province of Canakkale (Turkey). Merck Kits equivalent to EPA, APHA, ISO and DIN standards were used in spectrometric analyses. The monthly quality parameter results in this study were evaluated according to various limit standard values of different countries. As a result, NH₄⁺ cation and Al metal concentrations varied between 0.003 and 0.999 mg L⁻¹ (0.073±0.139 mg L⁻¹), 0 and 0.652 mg L⁻¹ (0.141±0.068 mg L⁻¹) respectively.

Keywords: Canakkale, Swimming pool waters, ammonium cation, Al metal

1. INTRODUCTION
Swimming is one of the most popular aquatic activities in industrialized countries. During busy periods, the quality of pool water may be compromised. Indeed, swimmers bring microorganisms and organic substances (saliva, sweat, cosmetics, sunscreen and urine) with them into the water, which strongly contributes to water contamination (Sakkas et al., 2003; Kanan and Karenfil, 2011; Keuten et al., 2012; Uysal et al., 2017).

Ammonia in water is an indicator of bacterial, fecal and animal wastes is being mixed into the water (Anonymous, 2006; Uysal et al., 2017). Pool water resources NH₄⁺, the filling water, human origin (fecal and urine contamination) and is caused by biofilm formation
Ammonium is just quickly oxidized to nitrite in oxygen environment and then transformed into nitrate. Nitrification is carried out by bacteria such as *Nitrosomonas* and *Nitrobacter* group bacteria (Mutluay and Demirak, 1996; Uysal et al., 2017).

Organic substances which cause water discoloration are usually removed from water by coagulation (clotting), precipitation and filtration (Yaşa, 1999; Uysal et al., 2017). Before the filtration, the stability of small particles (electrical) is deteriorated thanks to the addition of the flock material into pool water and hence agglomeration of particles is provided. For flocking, chemical (e.g. addition of colloidal substances such as Al₂(SO₄)₃ to water) is used (Bölükbasioglu, 1993; Uysal et al., 2017). The flocculation decrease chlorine consumption in the pool and hence eye diseases and BK formation which cause bad smell are avoided (Akkaya, 1993; Uysal et al., 2017). Aluminium (Al) is known to be non-toxic element. However, excessive amounts of intake have been shown to influence the nervous system and cause anemia. Al is an element also used in Alzheimer and diabetes diseases (Canadab, 2003; Uysal et al., 2017).

Limit concentration values of the Turkish Health Ministry for NH₄⁺ cation and Al metal are 0.50 and 0.20 mg L⁻¹, respectively (Anonymous, 2011; Uysal et al., 2017). In order to evaluate some quality standard levels of swimming pools found in the province of Canakkale (Turkey), this study on determination of NH₄⁺ cation and Al metal concentrations in water of swimming pools in center of Canakkale has been conducted in summer period (July, June and August, 2013) due to the intensive tourism activity in this period.

### 2. MATERIALS AND METHODS

#### 2.1. Study area and period

In this study, 6 swimming pools as a study area (Figure 1) were selected. Pool water samples were monthly collected from sampling locations (swimming pools) in summer period of 2013 (June, July and August, 2013) in Canakkale province (Figure 1). The sample numbers Çanakkale, 33-36 (Figure 1).
Figure 1. Water sampling points for swimming pool in the summer period in the provinces of Canakkale, Turkey (Sample numbers: Çanakkale, 33-36), (Uysal et al., 2017).

Pool water samples were collected from special points where the water flow is the lowest or swimmers are the most intense. Moreover, special sampling depths and points were just under surface (0.20 m) and about one meter away from the edge line of the pools. The collected samples were put in clean polythene sample bottles (1.00 L) and stored in deep freezer at -21.0 °C until analyses. In this study, samples from the total 6 swimming pools were analyzed for each parameter.

2.2. Analytical methods

In current study, NH4+ cation and Al metal concentrations in summer period were determined by ultraviolet-visible (UV-VIS) spectrophotometric technique in the total 6 swimming pools found in the province of Canakkale (Turkey). Thermo Aquamate Brand...
Spectrophotometer was used for analyses. For analyses, Merck Kits equivalent to EPA, APHA, ISO and DIN standards were used.

Ammonium nitrogen (NH₄⁺-N) occurs partly in the form of ammonium ions and partly as ammonia (Uysal et al., 2017). A pH-dependent equilibrium exists between the two forms. In strongly alkaline solution ammonium nitrogen is present almost entirely as ammonia, which reacts with hypochlorite ions to form monochloramine (NH₂Cl). This, in turn, reacts with a substituted phenol to form a blue indophenol derivative that is determined photometrically. The method is analogous to EPA 350.1, APHA 4500-NH₃ F, ISO 7150-1, and DIN 38406-5. Analysis measuring range is ranged from 0.01 to 2.00 mg L⁻¹ NH₄⁺ -N and 0.01 to 2.58 mg L⁻¹ NH₄⁺. In the production control, the following data were determined in accordance with ISO 8466-1 and DIN 38402 A51: Standard deviation of the method ± 0.0146 (mg L⁻¹ NH₄⁺-N), coefficient of variation of the method ± 1.40 (%), confidence interval ± 0.035 (mg L⁻¹ NH₄⁺-N), Sensitivity: Absorbance 0.010 A corresponds to 0.009 (mg L⁻¹ NH₄⁺-N), accuracy of a measurement value max ± 0.052 (mg L⁻¹ NH₄⁺-N) (Merck 2014).

In weakly acidic, acetate-buffered solution aluminium ions react with chromazurol S to form a blue-violet compound that is determined photometrically (Uysal et al., 2017). The method is analogous to APHA 3500-Al-B and DIN ISO 10566 E30. Analysis measuring range is 0.02 to 2.00 mg L⁻¹ Al unless otherwise stated. In the production control, the following data were determined in accordance with ISO 8466-1 and DIN 38402 A51 (10-mm cell): Standard deviation of the method ± 0.012 (mg L⁻¹ Al), coefficient of variation of the method ± 1.70 (%), confidence interval ± 0.03 (mg L⁻¹ Al), Sensitivity: Absorbance 0.010 A corresponds to 0.001 (mg L⁻¹ Al), accuracy of a measurement value max ± 0.008 (mg L⁻¹ Al) (Merck, 2014).

3. RESULTS AND DISCUSSION

The found concentration of NH₄⁺ cation and Al metal in water of swimming pools water in center of Canakkale, are giving in Table 1 and Figure 2,3.

Average summer results showed that NH₄⁺ concentrations varied between 0.003 and 0.999 mg L⁻¹ (0.073±0.139 mgL⁻¹). Based on both maximum and average values, NH₄⁺ concentration increased from June to August probably due to the increasing touristic population.

Average summer results showed that Al concentrations varied between 0 and 0.652 mg L\(^{-1}\) (0.141±0.068 mg L\(^{-1}\)). Although average Al concentration increased from June to August probably due to the increasing swimmer population based on both average values, maximum values of Al (0.6522 mg L\(^{-1}\)) was July and August, respectively (Table 2). However, although all maximum Al values were over the limit values for pool water standards of Turkish Health Ministry and the standards of some European countries, all average values were considerably under all these limit values (Table 2).

Figure 3. Variations of Al in swimming pool waters in the summer period in the provinces of Canakkale, Turkey (Sample numbers: Canakkale, 33-36).

Results revealed that Al concentrations varied between 0 and 0.6522 mg L\(^{-1}\) during the sampling period (Figure 3). Unhealthy pool water ratio for Al was calculated as 2.27%.

4. CONCLUSIONS

The results of NH\(_4^+\) indicated that there were suitable aerobic nitrification conditions due to the high dissolved oxygen concentrations in the pool waters. It is known that NH\(_4^+\) very quickly converts to NO\(_3^−\) due to the nitrification in aerobic conditions (Mutluay and Demirak, 1996; Putz, 2008, Uysal et al., 2017) and partly NH\(_4^+\) were under standard limit values (Table
1). In a study on microbiological and chemical qualities of 144 swimming pool waters (69 indoor, 75 outdoor) for three-year period (2010-2012) in Bologna (Italy), Dallolio et al. (2013) using same methodology (spectrometric method) in this study revealed that noncompliance rate to standard limit value (unhealthy pool water ratio) were 1.20 and 0.00% in the indoor swimming pool waters and outdoor pool waters, respectively (Uysal et al., 2017).

![Figure 4. Nitrification and denitrification (Pütz, 2008; Uysal et al., 2017).](image)

On the other hand, non-human factors such as birds and plants. It is known that faces of the birds contain higher nutrient values than faces of the human (Tiffany et al., 2015; Uysal et al., 2017). For solution of such problems, it is important to get sanctions and obligations for hygiene controls and periodic changes of pool waters in legal manner (Uysal et al., 2017).

As a result, due to the fact that Canakkale province has important tourism activity in Turkey, pool waters in such tourism regions should be monitor in view of not only chemical (NH$_4^+$ cation and Al metal) and physical quality parameters (Temperature, pH and DO), but also microbiological (Salmonella and Vibrio etc.) quality parameters (Uysal et al., 2017).
